TITLE OF THE INVENTION

WEB PRINTERS

BACKGROUND OF THE INVENTION

[0001] The present invention relates to web printers of the type that form images on webs carried at high speed.

Related Background Art

[0002] In the general types of printers that form images on webs, pin members of a tractor mechanism mounted on the printer are engaged with the feed holes disposed along the edges of the web, and the tractor mechanism is driven to feed the web as an image is formed thereon using the image forming section of the printer. After the web with the feed holes has been printed, however, the portions of the web along which these feed holes are disposed (usually along the left and right edges of the web) need to be cut off, and thus an increased time is spent after printing in obtaining the final printed matter. Also, the printer itself requires a tractor mechanism as a component thereof, which inherently results in a complex configuration. Such a cutting operation as mentioned above can be omitted by adopting webs that are free of feed holes, using a web feed roller mechanism instead of a tractor mechanism of the printer.

[0003] In this regard, for a printer that uses webs

that are free of feed holes and which forms an image on a web while feeding it by use of a feed roller mechanism, if this printer is of the type which operates in no higher than a middle-speed region in which only about 50 pages per minute are printed on A4-paper on a horizontal feed basis, printing not conspicuous in terms of print position offsets is possible since not too significant slipping occurs between the web and the feed rollers. If, however, the printer is of the high-speed type that is capable of printing more than 100 pages per minute or is of the ultrahigh-speed region type capable of printing more than 200 pages per minute, it is difficult with a conventional configuration to feed the web to the image forming section accurately; and, even when extremely thin paper, such as is often used for a dictionary, for example, is fed at a rate as high as more than 100 pages per minute, the need arises to very accurately control the tension, traveling position, etc. of the web being fed.

Summary of the invention

[0004] The object of the invention is to provide a printer that, irrespective of the web type, enables stable feed of the web at high speed and with high accuracy.

[0005] The object set forth above can be achieved by providing a printer having a buffer for adjusting the traveling position of the web under its slack status, a tension assigning unit for assigning fixed tension to the

web delivered from said buffer, a device for detecting the traveling position of the web delivered from said tension assigning, a skew correction unit for adjusting the skew of said web according to the output from said detection unit, and an image forming unit that forms images on the web delivered from said skew correction unit.

Brief Description of the Drawings

[0006] Figure 1 is an overall block diagram of the printer representing an embodiment of the present invention.

[0007] Figure 2 is a diagram showing the configuration of the control section in the embodiment of Fig. 1.

[0008] Figure 3 is an overall block diagram of another embodiment of the present invention.

Detailed Description of Preferred Embodiments

[0009] An embodiment of the present invention will be described below with reference to the drawings. Figure 1 is a schematic diagram showing an embodiment of the printer according to the present invention.

[0010] Numeral 1 in Fig. 1 denotes a web. Web 1 may be made from paper, a plastic film, or the like. Web 1 is inducted into a buffer unit 4 via guide rollers 2 and 3 arranged on the web feed route; the guide roller 2 is connected to a motor 2b via a timing belt 2a and is rotationally driven at a surface velocity higher than the

feed rate of web 1 and in the same direction as the feed direction of the web.

[0011] The buffer unit 4 is equipped with a storage area 4a for temporarily storing the web 1 being fed, one pair of rollers 4b and 4c provided at the web loading section with respect to the storage area 4a, one pair of rollers 4d and 4e provided at the web unloading section with respect to the storage area 4a, motors 4f and 4g for driving the rollers 4b and 4e, respectively, and a plurality of sensors (in this embodiment, three pairs of optical sensors 4h, 4i, and 4j) for monitoring the amount of slack of the web 1 in the storage area 4a.

[0012] The rotational speeds of the rollers 4b and 4e are controlled via the motors 4f and 4g according to the particular output of each sensor so that the amount of slack of the web 1 in the storage area 4a is restricted to stay within a predetermined allowable range. It is desirable for the roller 4e and the motor 4g to be provided so as to keep constant the torque being generated and conduct stable control of the torque required for the rotation of the roller 4e.

[0013] In the vicinity of the rollers 4d and 4e, located at the web unloading section of the buffer unit 4, there is provided a guide member 4k that restricts the edge positions of the web 1 being fed. Since the guide member 4k acts on the web existing under a stack status, the

traveling position of the web 1 in contact with the guide member 4k is easily adjusted. In this embodiment, the guide member 4k is provided so that the skewing width in the feed direction of the web can be restrained with a maximum margin of about 1 mm during the start of feed (this margin during stabilized feed can be about 0.5 mm). The tension of the web 1 at the initial phase of its feed is determined by the torque generated at the roller 4e and the take-up angle of the web with respect to guide roller (fixed roller) 5, and the lateral skew angle of the web can be restrained to a certain extent.

[0014] After web 1 has been pulled out from the buffer unit 4, the web is fed into a tension assigning unit 6 via the guide roller 5 mentioned above. The tension assigning unit 6 consists of an infeed roller 6c driven by a motor 6a via a gear 6b, a pressure roller 6d provided so as to be press-fittable against the infeed roller 6c, and a dancer roller 6e supported movably on the web feed route.

[0015] The pressure roller 6d is provided at one end of an arm 6f supported so as to permit oscillation thereof about a shaft 6g, and it is pressed against the infeed roller 6c by the elastic force of a spring 6h provided at the other end of the arm 6f. The dancer roller 6e is provided at one end of an arm 6j that is supported so as to permit oscillation thereof about a shaft 6i, and it is constructed so that any slight differences in the feed

rate of the web being fed are absorbed by the elastic force of a spring 6k provided at the other end of the arm 6j. The oscillating position of the arm 6j is monitored by a sensor 6m, and the rotation of the infeed roller 6c is controlled according to the particular position of the arm 6j, namely, the particular output level of the sensor 6m. In accordance with the present invention, the dancer roller 6e plays an important role in controlling the tension of the web 1 between the infeed roller 6c and an outfeed roller 15c (described in detail later in this document). That is to say, an image forming section 10 is located between the infeed roller 6c and the outfeed roller 15c, and this means that, if highly accurate tension control cannot be conducted at the dancer roller 6e, the printer will incur the fatal problem that image components of each color are transferred under a position-offset status on the web. In this embodiment, therefore, the tension of the web 1 between the infeed roller 6c and the outfeed roller 15c is adjusted by the dancer roller 6e so as to stay within the range from 30 to 200 N, depending on the ream weight and width of the print paper.

[0016] After that, the web 1 that was pulled out from the tension assigning unit 6 is fed into a skew correction unit 8 via a guide roller 7. The skew correction unit 8 is composed of two position-restricting rollers 8a and 8b provided in parallel, a sensor 8c for

detecting the edge position of the web 1, and a driving motor 8d. The two position-restricting rollers 8a and 8b are supported so that they can be rotationally moved under their parallel status by a frame 8d, and these rollers are provided so that both can be inclined together to the required angle by rotating the frame 8d through an angle based on the output level of the sensor 8c.

[0017] The web 1 that has been passed through the skew correction unit 8 is fed into the image forming section 10 via a guide roller 9. Although the present invention is not limited to use of a particular image forming section 10, this embodiment exemplifies an image forming section of the type which forms toner images on the photosensitive material by use of known electrophotographic processes, and employs a configuration where color images are formed on one side of the web 1 by four imaging portions, 10a, 10b, 10c, and 10d.

[0018] The structure of the imaging portions will be described below taking imaging portion 10a as an example. Numeral 101 in the figure denotes a photosensitive material belt. When the photosensitive material belt 101 starts rotating, a high voltage is applied to a corona charger 102 and the surface of the photosensitive material belt 101 is uniformly charged. The laser beam that has been emitted from a light source 103, including a semiconductor laser, photo-emitting diodes,

etc., provides the surface of the photosensitive material belt 101 with image exposure and forms an electrostatic latent image on the photosensitive material belt 101. When the photosensitive material belt area holding this latent image reaches a position that faces an image developing unit 104, a developing agent is supplied to the electrostatic latent image and a toner image is formed on the photosensitive material belt 101. The toner image that has been formed on the photosensitive material belt 101 is attracted onto web 1 by the action of a transfer unit 105, by which a charge of opposite polarity to that of the toner image is assigned to the reverse side of web 1. The area that has passed the transfer position of the photosensitive material belt 101 is cleaned by a cleaning unit 106 in order to prepare for the next printing operation.

[0019] In the way described above, after the toner image has been transferred from the four imaging portions, 10a, 10b, 10c, and 10d, to web 1, the toner image is fixed by the passage of the web through a heater 11, and the web is unloaded from the printer via guide rollers 12, 13, and 14, an outfeed roller mechanism 15, and a puller 16. After this, the web is carried to a post-processor (not shown in the figure), where the printer then performs the required processes, such as cutting, stapling, and punching, on the web in order to complete the series of operations.

[0020] In this embodiment, the outfeed roller

mechanism 15 is constructed similarly to the infeed roller mechanism mentioned earlier, and it consists of an infeed roller 15c, which is driven by a motor 15a and a gear 15b, and a pressure roller 15d, which is provided press-fittably with respect to the infeed roller 15c, wherein the pressure roller 15d is provided at one end of an arm 15f supported so as to permit its oscillation about a shaft 15e, and is pressed against the infeed roller 15c by the elastic force of a spring 15g provided at the other end of the arm 15f.

[0021] The printer in this embodiment is controlled by a control section 100. How the loop feed motor 4f, the infeed motor 6a, the driving motor 8d of the skew correction unit 8, and the outfeed motor 15a are controlled by the control section 100 will be described with reference to Fig. 2.

[0022] The loop feed motor 4f is driven so that its rotational speed changes according to the particular area of a print paper separating sensor on the basis of the digital signals of loop buffer storage volume monitoring switches (for example, optical sensors) 4h and 4j.

[0023] The infeed motor 6a has its rotation controlled according to the particular notch position of an encoder 6m provided at the dancer roller 6e, and it is driven so as to keep the position of the dancer roller 6e (that is to say, the tension of the print paper) constant.

[0024] The driving motor 8d of the skew correction

unit 8 is driven according to the particular output level of the paper edge detection sensor 8c, and it controls the position of the paper unloaded from the skew correction unit 8. Thus, the position of the paper fed to the image forming unit 10 is maintained stably.

[0025] The number of slits in the encoder 18g of a speed detection roller 18 during a fixed time is counted by a slit counting section 102. The speed of the outfeed motor 15a is changed according to the particular count value in order to minimize the effects of the constriction of the paper at fixing section 11 and the effects of increases in the circumferential speed of the outfeed roller 15c, associated with the heating of the outfeed roller. That is to say, the effects of the heat generated by the fixing section 11 can be suppressed by changing the speed of the outfeed motor 15a.

[0026] The heater 11 has a plurality of heating plates so that it can supply thermal energy to web 1, and this heater maintains its internal air temperature in the range from 150 to 350 degrees C and heats the web 1. If the image forming section uses ink jet processing, rather than electrophotographic processing, the heater 11 can be used as a means of drying the ink image recorded and formed on the web 1 during ink jet processing, and the internal air temperature of the heater 11 in that case is managed to stay within the range from about 40 to 150 degrees C.

Numeral 16a in Fig. 1 denotes the motor for driving the roller which constitutes the puller 16; and, similarly, numerals 17 and 18 denote the pressure roller and the speed detection roller, respectively, wherein the pressure roller 17 and the speed detection roller 18 are constructed as the so-called "coupled rotating rollers" that rotate simultaneously when coming into contact with the web 1 fed to both. Also, the rotating shaft of the speed detection roller 18 has a slit-provided disc (encoder 18g) and is so constructed as to detect the corresponding slits by use of optical sensors or the like. The rotational speed of the outfeed roller 15c is controlled by the control section 100 of the printer in accordance with the output signals of the above-mentioned optical sensors within a preset period, and thus the tension of the web passed through the image forming unit 10 is controlled. That is to say, when a signal indicating that the feed status of the web has been detected in its delay direction is obtained from the speed detection roller 18, the rotational speed of the outfeed roller 15c is increased, and in the opposite case, the rotational speed of the outfeed roller 15c is reduced.

[0027] According to the printer having the above configuration, since web tension between the infeed roller 6c and the outfeed roller 15c is controlled by the dancer roller 6e, and thus the feed of the web 1 passed through the image forming section 10 can be stabilized, high-

quality color printing not prone to shifting in terms of image position can be implemented.

[0028] Although the description set forth above assumes a configuration in which four imaging portions are arranged in line on one side of the web, four imaging portions can also be arranged on the other side of the web to apply the present invention to a printer capable of forming color images on both sides of the web. In this case, arranging at alternately different height levels the four imaging positions provided on one side of the web 1, namely, 10a, 10b, 10c, and 10d, and the four imaging positions provided on the other side of the web 1, namely, 10e, 10f, 10g, and 10h, as shown in Fig. 3, enables the printer to be practical because the height of the printer can be prevented from increasing too greatly and because its design can be made compact.

[0029] As set forth above, according to the present invention, high-speed and highly accurate feed of the web that passes through the image forming unit can be stabilized, irrespective of the web type, since the web printer has a buffer for adjusting the traveling position of the web under its slack status, a tension assigning unit for assigning fixed tension to the web delivered from said buffer, a device for detecting the traveling position of the web delivered from said tension assigning unit, a skew correction unit for adjusting the skew of said web

according to the output from said detection unit, and an image forming unit that forms images on the web.
